E-LEARNING PLATFORM SALES ANALYSIS

Project overview

This project uses a relational MySQL database with learners, courses and purchases. Primary and foreign keys connect learner and course records to each purchase. INNER JOIN, LEFT JOIN and RIGHT JOIN queries present purchase details and preserve learners or courses that may not have matching purchases.

Key findings from the sample data

- Total recorded revenue is $6,488.00 across 8 purchase records.
- Excel Mastery leads by quantity with 4 units sold. SQL Basics and Digital Marketing follow with 3 units each; the third-place position is a tie.
- Data Analytics generates the highest category revenue ($3,093.00) and has 3 unique purchasing learners.
- Programming generates $1,598.00 from 2 unique learners; Marketing generates $1,797.00 from 2 unique learners.
- Ben Carter has the highest learner spending ($1,997.00), followed by Asha Kumar ($1,397.00) and Chen Wei ($1,298.00).
- Ben Carter and Chen Wei have purchased courses from more than one category.
- UI/UX Design has no purchase records, identifying a course that may need more visibility or a review of its offer.

Recommendations

- Prioritize campaigns for Data Analytics, the highest-revenue category, while using Excel Mastery's unit-sales lead in promotional bundles.
- Promote UI/UX Design through introductory offers, previews or cross-selling to learners who have already bought related digital courses.
- Use category-based recommendations to encourage repeat purchases and cross-category learning, especially for learners who have bought from only one category.
- Track monthly revenue, units sold, average order value and repeat-purchase rate as more transactions are collected.

Conclusion

The sample analysis shows how relational joins and aggregate SQL queries can reveal revenue performance, learner spending, category popularity and courses with no sales. These insights can guide targeted marketing and course portfolio decisions. The figures are based only on the illustrative sample records and should not be treated as actual platform performance.
